The ESRI Survey of the Attitudes of Post Primary Teachers and Pupils

Volume I: General Background Volume: Background To and Over View of the Survey; The Setting of the Enquiry: The Schools, Teachers and Pupils surveyed; Technical Appendix on the Sample.

John Raven, Brian Ilannon, Ruth Handy, Ciaran Benson, Keith Wiason and Eamonn Henry.

EI/GBV/1/2

## I. i.

## Acknowledgements

We are most grateful to the following people without whose help this survey could not have been undertaken:

Mrs Colbert-Stanley, Mary Judge, Fiona Clarke and their teams of interviewers, coders and punch girls.

Mrs Dempsey and the Secretarial staff of the ESRI.

The ESRI advisory committee on educational research.

The UK Government Social Survey who supplied a copy of the surveyanalysis programme, without which there would have been still more extensive delays in the analysis.

Mr. Brian Mac Cumhaill who translated the questionnaires into Irish.

The CEO's who supplied names of teachers.

Mr. Gillespie and other members of the staff of the Department of Education who answered numerous queries and took on extra work to make the survey possible.

And, above all, the many headmasters, headmistresses, teachers and pupils who consented to be interviewed.

Although it would, in some ways, be desirable to delay publication of all the results from the ESRI survey of the attitudes of teachers and pupils until a comprehensive and integrated picture could be presented, this would delay publication of useful material. We have therefore decided to release reports on sections of the material as the analysis is completed. The final volume in the series will bring the material together and highlight the main issues offering such interpretations of the overall data as seem to be warranted.

In addition to the present volume three other volumes are well on the way to completion, and it is hoped to publish them shortly. These are: Volume II: Teachers' views on Examinations, Volume III: Teachers' Perception of Educational Objectives and Volume IV: Pupils' Perception of Educational Objectives.

In addition to the published volumes each volume has a companion document containing additional appendix material. These special appendixes are available on request from the ESRI. The additional tables they contain are referred to in the text with the prefix "SA". When ordering these Special Appendices it is essential to state the volume for which they are required.

II : The Interview Schedules and Questionnaires used in the Survey.
purpose of this volume

The purpose of this volume is to serve as a companion volume to the series of papers that are emerging from this survey. Although it presents basic data about the educational system which is not available elsewhere it has a still more important purpose in the context of the present survey: it presents material which may be of considerable importance in that, in the light of this data, readers may arrive at interpretations of the data to be presented in the other volumes which are very different from those we have presented. The report describes the way in which the survey came into being it describes the topics to be covered in the subsequent reports; it discusses the level of statistical significance which may be attached to the results; it attempts to give a birds-eye view of the schools, the teachers, and the pupils involved in the survey (and as such may lead to interpretations of the data which have escaped our attention); and it describes the way the sample was drawn and gives evidence concerning its representativeness.

## Origin and Advisory Commitiee

In the Spring of 1969 the Development division of the Department of Education approached the ESRI concerning the pussibility of conducting a survey of post-primary teachersl attitudes, role definitions, and the problems they encountered in the course of their work. Funds for the fieldwork, but not Institute staff or supportirg services, would be provided by the Department. The stimulus to their enquiry was Sean Kelly's (1967) study of National School teachers. The Department made it clear that they wished the enquiry to be objective in the sense that neither the data collected, nor the reporting of the results, should be subject to the sort of distortion which might creep in if the enquiry was conducted by someone directly attached to one of the mair bodies concerned with the administration of education in Ireland.

Once the ESRI had expressed a tentative interest in the enquiry a meeting was held with members of the Department. A preliminary list of topics which it might be desirable to investigate emerged from that meeting. Thereafter, in order to in order extend this list, that is/to assist the institute ensure that the enquiry did not neglect to cover issues which one section or another of the teaching profession considered important, and subsequently to ensure that the researchers did not overlook aspects of the data which contained material of importance to one or other sectors of the teaching profession, an Advisory Committee was set up. On this there are representatives of the Joint Managerial Body of Secondary Schools, The Teaching Brothers Association, The Conference
the Association of Secondary Teachers of Ireland, the Irish School Masters Association, the Association of Irish Headmistresses, the Catholic Headmasters Association, the Federation of Catholic Lay Secondary Schools and the Department of Education.

The preliminary list of topics to be covered was circulated to the Advisory Committee and the contents of the survey discussed with them and modified in the light of the opinions expressed. In particular it was felt that the enquiry would greatly benefit from extension to include material collected from pupils. Although the Department of Education had no funds avaliable for such an extension the ESRI felt that, if the survey was to be carried out at all, it would be a mistake not to make use of this opportunity. Funds were therefore made avallable from the ESRI budget to finance collection of this data by means of self completion questionnaires from the pupils. Although it would have been far preferable to collect this material through personal interviews with pupils the ESRI unfortunately did not have sufficient funds to finance the enquiry. on this basis. As will be seen later this has had unfortunate consequences for the quality of the material obtained from the pupils.

## Exploratory Phase

In addition to setting up an Advisory Committee of senior people to draw the researchersi attention to topics and problems which the researchers had overlooked, the Institute also carried out its own exploratory work at the "grass-roots" level among teachers and pupils.

Such programmes of exploratory work represent one of the most crucial stages of any social survey: one can distort what appear to be the results of an enquiry as much by not asking the right questions as by suppressing results.

The execution of this exploratory work is no simple matter. One is looking for topies which one has not yet noticed but which ought to be included in the enquiry; one is looking for hazards which will impede one in distant days in reaching a goal which is not yet clearly formulated. One cannot ask people to draw one's attention to these things, not only because they do not know what one knows, but also because they are so familiar with many of their problems that they come to regard them as inevitabilities of life.

Under theso circumstances the best that can be done is to try to interview a wide range of different sorts of people in the hope that the contrast between what one person says and what another says (or does not say) will somehow force important issues upon one's attention. In the early stages these discussions are allowed to range freeiy: often these conversations move away from a specific focus on the topics covered In the stated purpose of the survey to others which are important to the informants in their lives as a whole. These conversations are not so irrelevant as they often appear to informants, since the attainment of general life goals is for many people intimately tied up with their jobs, and their problems and satisfactions in their joos can only be understood in the wider context of their life goals.

## Examples of Question Formulation it: The Depariment"

We may lllustrate the process of question formulation and development with two examples which are particularly important in the context of this survey. One concerns attitudes to the Department of Education, the other the list of objectives in education.

It became clear very early that "The Department" (of Education) was a salient feature in the minds of teachers. At first brush it seemed that attitudes toward the Department were in general negative. It would have been very easy to have included in the survey a question concerning attitudes to the Depariment, the answers to which would have shown that the teaching profession, did, in general, hold negative attitudes toward the Department. However further listening revealed that such a conclusion would have been entirely misleading. For in some ways teachers thought very highly of the Department. The problems we were then left with were, first, to decide what were the minimum number of dimensions that it would be necessary to cover if one was to obiain a fair picture of what teachers thought of the Department, and, second, how to phrsse the questions concerning each dimension in such a way that teacherst feelings concerning one dimension did not contaminate their answers concerning other dimensions. Although unambiguous statements made by teachers were utilized in framing the questions, the results of the pilot survey in relation to a few items were felt by some advisors to be too sensitive and open to misinterpretation. These items were duly altered.

#### Abstract

#### Abstract

are so specific that they entail a very long list, There Was an additional constraint in that we hoped to extend thenguiry to pupils. This entailed that the objectives be phrased in words that they, too, would understand. Complex aducstional concepts hat therefore to beremprased in relacively simple terms. Fortusstejyg during the explomatory wark with pupils, many of theae same dakas Were expressed by the papils themselves in words which could be ased in the main ouryey.

The list ot objectives utilimed in this survey, has, in fact, evolved through exploratory work carried out, not only in connection sith this survey, but also in connection with the British Young School Leavers (Morton Williams et al 1968) and Sixth Fomm (Morton Willams et al 1971 ) enquiries (both these age groups being represented in the single Trish enquiry) and the statistical anglyes earried out in these two previous surveys.

#### Abstract

Once a revised list enr ase in the Irish survey had been obtained it was tried out on s pilot basis and items which were highty correlated with each other and therefore similar in content) of uncorrelatod with anything else (and therefore probably meansugless) renoved in order to ensure that we had a list which was as short but as comprehensive and meaningeul as possibla.

Special Objectives of the Survey of Pupila

The survey of pupils had, in some ways, more fundamental aims than the survey of teachers. The surveg of teachers attitudes was guided by the broad aim of assessing their perception of educational objectives, With a view to helping educationaliste take a step back from their everyday tasks and agk tif these are the. objectives we should be aiming at, are we going about it in the hest way?". (Or, alternatively, "Should teachers be mainly concerned about these things?") *

This may be contrasted with the aim of the pupils ${ }^{1}$ enquiry which was basically to collect information which would make it easier to generate educational programmes geared to the pupils' feil needs, the backgrounds from which they came, their attitudes and values and to their career aspirations and the life styles they were likely to adopt and which could take into account their reactions to the subjects they were studying at the time of the enquiry, their reactions to the existing school system. It was hoped, too, that it might be possible to use che data to distinguish between ditferent groups of pupils who appeared to have different needs. In addition to collecting data relevant to this basic aim information was sought concerning the development of their perceptions of a number of careers.

Stages of the Enquiry

As has already been indicated the enquiry went through exploratory, pilot, and main survey stages. At each stage the material to be collected and the results obtained to date, were discussed with the advisory committee.

## 1. Exploratory Stage: Population Interviewed

During the exploratory stage Raven and Hannon visited a number of schools selected to cover most of the groups which would eventually be represented in the main survey, but not in proportion to the total number of pupils in those types of school. These schools, which were located in various parts of the country, included Secondary, Diocesan and Religious Order schools, Convents, Teaching Brothers Schools, Vocational Schools, Comprehensive Schools, and Protestant Schools. Large and small schools in both
urban and rural locations were selected with a wide geographical distribution. In these schools free-ranging decussions were held with indiridual teachers and groups of pupils. In all some 50 tenchers and 100 pupils were interviewed. These discussions moshly lasted one school period, but sometimes much longer. Following these discussions plot questionnaires were drafted.
2. Pilot Stage

Pilot work, carried out with the intention of cutting down the length of the questionnares and spotting ambiguous questions, was conducted in eleven schoois. 72 teachers were interviewed and 175 pupils completed questionaires. Statistical analyses were made of the answers to most questions and the results diseussed with the Advisory Committee. It should be noted, however, that the sample was once more not representative of the total popularion, but drawn to cover the main types of school present in the different areas of the country. As a result of this wort the length of the questionnaires was reduced by about one-third. Part of his saving was achieved by dropping a section which was concerned with trying to gather some data to answer the question "Who are the teachers, what are their general atitudes to life"? Items in this section were drawn from a battery of attitude items in the course of development as part of the Institute's general research programme. It was dropped from the Education survey mainly because it failed to produce a clear factorial structure at the pilot stage. However further work on this pilot data has been carried out and has turned out to be of considerable value and has since been published.*

[^0]
## 3. Main Suryey

#### Abstract

Ge first give ap overvisw of the enquiry and then move on to give more tequik. During october December 1970 1,24 teachent were interutewed and d. 222 papils in thena thind oe subegucnt yoat of post... primary edncation completed questionnaires. The sample excludfatearhere and pupile in secondeny tops, Domestic Sctence Colleges, Commercial Colleges, and Religous

 Seminaries. The informants were located in a national Fepresentatiote sample of hat schoole. In adition to being interriswed, teachers (but not head tenciners). also completed written questionamires in which furfber topics were vovered.The faterviening fas saried out by trained interviewers from the ESily survey unit who has been briefed over a 2 day proriod in connection with this partiendar aqryey.

In order to seep the length of interviewg to a minimum there were three aiternative verisions of the teacher interview, tuo of the teachers selfmempletion booklet, and three alternative versions of the pupil questionnaires. These various versions bad sevenal topics in common, but in other pespects the different versions covered different subject matter. As a result certain important data has been obtained from the whole sample while other materifl has been obtained only from a third or hale of the informante.

Irish Language versions of the Teachers Interview schedule (version $X$ ) and form 1 of the pupil questionnaire were prepared by Brian MacCumhai.11.

16 Pupilf in two schools completed Irish language versions of the questionnaires and 7 teachers were interviewed in Irish.

The Samples and Weighting of Responses

The samples were drawn on multi-stage, multi-stratified basis with ovevsmpling of small but important categorios. Details are given in the Appendix entitled "Technical Appendix on the Samples".

Sampled teachers were teaching more than 15 hours pex week (unless they were head teachers) and pupiis wexe in their third or subsequent year of post primary education. The weighted distribution of the samples of schoois, tewhers and pupils correspond elosely to National statistics, giving one avery confidence in the respresentativeness of the samples. Attention should be drawn to the fact that, atthough the sample is representative of pupils in their third or subsequent year it is not representative of papils aged $13,14,15,10$. and 17 in the sohool going population.

The 10 and 14 yeac olds inoluded in the sample cannot be anything other than atypical 13 and 4 year olds.

In all $124 ;$ teachers were interviewed, and 4222 pupils completed questionnaires, in 161 schools.

Since it was important to get large enough numbers of teachers and gupils within protertant ad corprehensive schooiz, and sed yemp pius papile in Focational schoole to permic iag to generaitae about the views of teachers gat pupils falitog into these catogoriea these popajations had to be over sampled. In Comprehensive schools 5 beachers and pupils were incerviened for gvery one that bhould have been interviesed on a proportional basis. Tn protestant ansools the figure wes 5 to every 3. Anong Yocational 3chool pupits it was 2 for every 1. In ealculating the fing fogtres, therefore, the regponses op thase teachers and papils hed to be weighted downwards to the true groportions. The result ig that the 53 teschers interviewed in Comprehensive schoola were treated ab if they were only 11 and the 7 teachers interviawed in Protestant achools were weighted down to 4. The effect of this ie that, although we can attach much more aignificence fo the regults relating to these groups than would otherwise bo the case. the overall figures are not hiassed in thets favour, The "weighted" figures given in the tort are the eigures otidined after this correction has been made.

The Interview Schedules and Questionnaires

The interview schedules and questionnaires will be found in the special appendix.

These comprise:

1. A form on which information about the schooi was recorded.
2. Three alternative forms, $X, Y$ and $Z$, used for the interviews with the teachers. A list of the questions common to $X, Y$ and $Z$ and the questions specific to each is also given in the appendix. In was necessary to have three alternative forms of the teachers' questionnaire in order to cut down the amount of time needed for the interviews and to ensure that sufficient data was collected on the most important topics.
3. Teachers Self Completion Forms A and B. Again, for the game reason it was necessary to have two alternative forms, each teacher being asked to complete only one.
4. Four forms, 1, 2, 2 C. 3. and 3 for pupils. These forms are again very similar. In particular there is a very alight difference between Forms 2 and 2 C. B., the latter being a special form for use in schools run by the Teaching Brothers Association.

The data collected falls into the following main areas:

## Teachers:

1. Their perceptions of educational objectives and the success with which they feel they attain these.
2. Their perceptions of examinations, the functions these are thought to perform, and the subject sylabii.
3. Their perceptions of their pupils' values and the lives for which they think they are preparing their pupils.
4. Their satisfaction with school teaching as a career.
5. Their feelings about educational policy, its formulation, and administration.
6. Their involvement in, and understanding of, curriculum developments and educational innovations.
7. Their attitudes toward, and involvement in, pupil guidance and discipline.

Data was collected from teachers on two occasions: once in the personal interviews (forms $X, Y$ and $Z$ ) and once by means of a selfcompletion questionniare. Head teachers were not asked to complete the latter; 893 (weighted) teachers did so.

## Pupils:

1. Their perception of educational objectives and their school subjects.
2. Their educational and occupational aspirations.
3. Their values and the sorts of satisfactions they would like out of their careers.
4. There reactions to rewards and punishments in school.
5. Their use of libraries, clubs and social facilities.
6. The images they hold of themselves and of various careers.

## Chapter II

The Setting of the Enquiry: the Schools, the Teachers and the Pupils Surveyed

The object of this chapter is to present a general picture of the schools in which the pupils involved in the survey studied and in which the teachers worked. It provides a context for what is to come later, a context which may suggest interpretations of the attitude material which are very different from those we offer. It also provides basic data about the educational system which is not avallable elsowhere.

Although, within school types, the sample is representative of the total populakion of post-primary schools in Ireland, the number of Protestant and Comprehensive schools is small. Since all comprehensive schools in the country at the time of the survey were included in the sample the information concerning them is complete. Although one can be fairly confident that the samples of Catholic secondary and Vocational senocls are representative of the total populations of such schools this is less true of Protestant schools, because only 10 such schools were included in the smmple.

Although the findings may not generalise because of the small numbers of Protestant schools in the sample we describe the characteristios of these schools in some detail because these characteristics may explain some of the difference between the responses of informants in different types of schools which will be discussed lator in this report. Likewise we give details of the Comprehensive schools; idiosyncratic responses of the teachers and pupils in such schools may be due, not to twact fact being comprehensive, but to the particular oharacteristics of such schools in this sample.

## I The Schools

Of the 161* schools which took part in the enquiry 65 were co-educational, 45 of these being vocational schools. The percentages of pupils attending coeducational and single sex schools of the various types were:-

[^1]TABLE 1. Percentages of pupils attending mixed and single sex schools of each type.

## Location and Size

For the purpose of this survey rural schools, which might better be described as "comatry" schools, were defined as schools outside educational centres containing more than 1,000 post primary pupils. This is roughly equivalent to schools outgide towas of 4,000 people.

It can be seen from table A1 (in the appendix to this chapter) that, by this definition $61 \%$ of the schools were rural, although only $46 \%$ of the pupils attended them. Of these rural schools over half were small, consisting of 200 or fewer pupils. In this they were unlike the urban schools of which only $20 \%$ fell into that category (Table A2). Most of the vocational schools, and $57 \%$ of the Catholic secondary schools were rural as compared with only $10 \%$ of the Protestant schools. A slightly higher proportion of the Protestant and vocational than Catholic secondary schools had 200 or tewer pupils. (Table A3)

## Subjects, Facilities, and Societies Available

The choice of subjects and the facilities and educational equipment available to pupils appears to depend both on the type of school which they attend and, to a lesser extent, on the size of the school (Tables A4 and A5), In our sample, the pupils attending Protestant schools appeared to come off best on both of these counts as $80 \%$ of such schools offered a relatively wide range of subjects, including science and at least 2 modern languages other than Trish, up to Leaving Certificate standard, while $44 \%$ of the Catholic, $50 \%$ of the comprehensive and only $6 \%$ of the vocational schools, did so. The latter of course were more likely to offer a wider selection of practical subjects than the other types of schools with the exception of the comprehensives. Table AG gives the percentages of schools not teaching the main subjects regarded as optimal extras by the Minister for Education. Obviously the figures available for the various science subjects must be treated
with care as a school which teacher science $A$, for example, may not have indicated that botany and zootogy were taught although they in fact form an integral part of the syllabus for science A. It is interesting to note that $39 \%$ of the schools in the sample did not teach art and $45 \%$ did not teach music.

The comprehensive schools in our sample were all relatively well supplied with equipment, specialist rooms, gymnasia ete (Table A7). Thay all had at least 5 items of basic equipment such as reoord players, T. V. sets, projectors etc, a libeary, a staffroom, a dining room and/or a hall with stage, a science laboratory, at least one kand/eye roorn and one or more other specialist rooms, a gymnasium and/or playing fields. The Protestant schools were twice as likely to have such facilities as the Catholic schools, while the vecational sehools and schools of 200 or fewer pupils fared least well under this heading. It is interesting to note that $96 \%$ of the schools had tape recorders, $84 \% \mathrm{~T} . \mathrm{V}$. sets, $83 \%$ slide projectors but only $48 \%$ had radios. As expected the specialist room least frequently available was an equipped language Jaboratory ( $10 \%$ had one) but surprisingly this was closely followed by an equipped gymnasium, which $24 \%$ of the schools in the sample possessed, the figure being $13 \%$ in vocational schools. It is probably advisable to point out that we had no means of assessing the quality of the equipment and facilities provided: "equipped gymnasium", for example, can mean a number of different things.

As would be expected most vocational schools had adult education classes but otherwise the schools provided little by way of adult education or community activities (Table A11). Two fifths had no such activities. Only $14 \%$ had a parent-teachers association.

39 of the 163 schoote han sone pupils as boarders but of these only 14 hed more then $50 \%$ of their total numbers as boarders and these 14 wexe neariy all smallex schools of 300 pupils or less (Table SA 1, in the special Appendix available from the ESRI).

The size of the gchools seems to be an iroportant factor determining the number and variety of clubs and societies available to pupils (Table A 8 ), the larger schools in the sample being much more likely to organise such culturat pursuits as Debating Societies, Drama Clubs, Special Interest Sociaties and Crafts and Fobbies, Two thirds of the schogle had some form of Sports Club and size did not seem to have much influence in this respect. The vocational schools (Table SA 2) on the whole seemed to offer the least varicty of types of clubs, although slightly fewer of them than of the . Catholic secondary schools, organised no clubs or societies. Almost a quarter of the Catholic secondary schools had no clubs or societies while all the comprehensive and Protestant schools had some form of society ox club.

As might be expected, the smaller schools, that is those with 200 or fewer pupils, had the best staff/pupil ratios, almost half of them having 1 teacher to 15 or fewer pupiis as compared with only 16 per cent of the schools with more than 400 pupils (Table A. 9 ). So fan as school type was concerned, the Protestants and comprehensives were most likely to have the best ratios while the Catholic secondary schools were more likely than the other school types to have 1 staff to 16 or more pupils.

Reference to Table.SA 4 hows that: Catholic secondary schools and Protestant schools were more likely than

## ST \& P 6

vocational and comprehensive schools to have more than a quarter of their staff aged over 40. They were less likely to have more than half of their staff aged between 26 and 40 , and less likely to have more than $20 \%$ aged 25 or less. Thus the general age of the staff in these schools was unmistakably older.

Allocation of Pupils to Classes

In about one third of the schoois the 1st year classes were streamed but there were quite large differences between the school types, the comprehensive and Protestants schools in the sample being much more likely to have mixed ability classes without either (Table SA 5)
setting or streaming in the list year./ However, the majority of the schools which did not have streaming or setting in 1 st year, did not persist with a common course throughout the junior cycle but used setting, streaming or group teaching after an initial period of settling down. Just under one third used setting or streaming while the same number used group teaching methods after the first year.

Within the sample of schools just described 153 head teachers and 1,093 other full-time teachers were interviewed individually. When responses from teachers in the over-sampled comprehensive and Protestant schools were weighted downward the final figure emerges as a total of 1,175 of whom 146 were head teachers. The majority of this weighted sample ( $67 \%$ ) were teaching in Catholic secondary schools, $29 \%$ were attached to vocational schools and only $4 \%$ and $1 \%$ respectively were in Protestant and comprehensive schools. They were relatively evenly distributed amongst the single sex and co-educational schools, and between urban and rural schools. The greatest number ( $47 \%$ ) taught in schools of between 201 and 400 pupils with $28 \%$ in schools of 200 or fewer pupils.

Of the total sample $56 \%$ were men. $36 \%$ of the women were nuns and $21 \%$ of the men belonged to religious orders. In Catholic secondary schools all the head teachers were religious although religious teachers comprised only $43 \%$ of the total staff of some schools. (Table A10).

The average age of the teachers was 36 . The staff interviewed in vocational schools were on average younger than the others (table SA 7). In spite of the fact, that, as we have seen, the total staff of the comprehensive schools were younger than others, this was not true of the sample of teachers interviewed, $34 \%$ were married. $95 \%$ were Catholics.
$78 \%$, in comparison with $69 \%$ of the pupils, had fathers whose occupations fell into Hall Jones categories 1-4. However, in relation to the total population, social classes $3 \& 4$ were over represented in the teachers ${ }^{\prime}$ backgrounds, and classes 7 \& 8 underrepresented (table A14). Again, in comparison to the total population, proportionately fewer teachers came from Dublin and more from the rest of Munster, from Galway and from Mayo. (Table A15). Nevertheless the social origins of post-primary teachers are obviously not so strikingly different from those of the total population as those of National School teachers (Kelly, 1970). ${ }^{1}$

1. Sean C. Kelly, Teaching in the City, Gill and Macmillan, 1970, Chap. V.

Teachers who were not heads were asked if they held any position of responsibility. $64 \%$ said they did not. Teachers in Protestant schools were most likely to say that they did and those in comprehensive schools least likely to say they did (table SA 6), These differences may arise from differential understanding of "posts of responsibility", although the following random selections from the posts of responsibility listed by the teachers suggests that this is not the case. At the time of the survey, while much discussed, posts of responsibility had not yet been allocated in comprehensive schools.

| Protestant Schools | Catholic Schools | Vocational Schools |
| :---: | :---: | :---: |
| Head of English Department | Bursar | School organiser (time table etc.) |

| Tutor | Guidance teacher | Exam secretary |
| Form mistress | Librarian | In charge of garage apprentices |
| Senior Latin teacher | Games master | Registrar |
| Teacher in charge of discipline | Senior Layman | Promoter of Irish activities |

Twenty head teachers were not teaching at all and 13 of them were teaching less than 9 hours per week. $39 \%$ of the total sample of teachers taught between 21 and 24 hours per wieek, and $30 \%$ over 24 hours, $67 \%$ of the vocational school teachers falling into the latter category. $36 \%$ of the men as against $23 \%$ of the women taught more than 24 hours per week. (Table SA 8).

## Experience and Training

Almost a third of the teachers had never taught in any other school than the one they were in at the time of the interview. A quarter had been teaching there for more than 1 but less than 3 years. $44 \%$ of the teachers in the sample had taught for over 10 years while over a third had from 3-10 years experience of teaching as a career (Table SA 9 ) Almost a third had taught in another type of school from the one in which they were teaching at the time of interview.
$32 \%$ had held jobs outside of teaching which they felt had been of particular value to them as teachers such as carpentry, joinery and building, ( $23 \%$ of those who had other jobs) or office work, ( $21 \%$ ). The vocational school teachers were the mosi likely to have had this experience particularly of skilled manual type jobs, and the Secondary Catholic/school teachers the least likely (Table SA 10. The main value of such jobs was that it gave teachers some experience of actual working conditions, particularly appreciated by vocational school teachers: and some knowledge of how the adult community thinks and works.

The teachers qualifications were varied. The majority ( $64 \%$ ) had a degree and 7 . Dip. Ed, , but there were a few who had attended a 2 year Teacher Training Course only and some $9 \%$ with no teacher training whatsoever (Table A. 12). Others had additional qualifications such as Licentiate in Philosophy or a Diploma in Publie Administration. Very few teachers had not had experience of teaching the examination classes in their present schools, only $7 \%$ and $8 \%$ of those who taught in schools offering such courses had never taught the Group or Intermediate Certificate classes respectively and only $13 \%$ of those who taught in schools which took the Leaving Certificate had not had the experience of teaching the examination classes.

## Subjects Taught

the teachers, on average each person teaching 2-3 subjects. The most frequently taught subject was English ( $27 \%$ ) closely followed by Eeligious Instruction ( $27 \%$ ), Ilathematics ( $25 \%$ ) and Irish ( $24 \%$ ), Mathematics appears to be more common among male teachers than amo females, the respective figures being $30 \%$ and $18 \%$ while the teaching of French is obviously regarded as a more suitable feminine occupation, the figures there being $8 \%$ and $21 \%$ respectively. On the basis of their answers to the question asking them to list the subjects they wore reaching currently, the teachers were classified as Language and Humanity specialists, Mathematics and Science subject specialists, practical/ specialists or those who taught subjects (apart from Religions Instruction and Civies) drawn from 2 or more of these groups. The following table shows the percentages falling into each category.

TABLE 2.

Subject Areas Taught

|  | \% of all Teachers |
| :--- | :---: |
| Humanities and Languages only | 44 |
| Mathematics and Science only | 16 |
| Practical subjects only | 14 |
| Non specialists | 26 |
| Not Teaching | 1 |
| Weighted base $(=100 \%)$ | 1,174 |

There were interesting combinations of subjects taught. For example the subjects combined most frequeatly with Latin were English, Mish and history; with geography, history, English and Trish, and those teaching art or music most olten combined this with English, geography or Latin. Rather surprisingy only 9 of the 220 geography teachers also taught one of the sciences.

The Pupils

The 4, 222 pupils, who were in their 3 rd or subsequent year of post-primary education (intercert year plus), was made up of 2,069 boys and 2, 153 girls. As previously explained, the vocational school pupils and the comprehensive and Protestant schools having been over sampled, it was necessary to weight the responses of such pupils by $1 / 2,1 / 5$ and $3 / 5$ respectively to make the proportions in each school type in the sample correspond with national statistics.

The numbers and percentages of pupils attending each type of school included in our sample is as follows:

TABLE 3 Numbers of sampled pupils in each school type

The pupils interviewed ranged in age from 13 to 19 , the majority being 1.5 or 16 , and they were all in their 3rd or subsequent year of post-primary education. Their age distribution is shown in the following table:-

TABIE 4

Age distribution of pupils by sex

Boys
\%

Age in years

| $12-13$ | 2 | 2 |
| :--- | :---: | :---: |
| 14 | 15 | 15 |
| 15 | 31 | 31. |
| 16 | 29 | 30 |
| 17 | 18 | 16 |
| $18+$ | 4 | 5 |
| No answer | 1 | 1 |
| Weighted base $(=100 \%)$ | 1,654 | 1,791 |

It will be seen that to all intents and purposes we were dealing with a sample of 14 to 17 year olds (Table A. 16).

## Social Class Backgrounds

The pupils were asked to state the name of their fathers job and give a brief description of the work done by him. Later these ocupations were classified according to the Hall-Jones Scale of Occupational Prestige for Males,* which uses 8 ategories. The social class groupings used, with a few examples of the occupations in each, were:-

[^2]

Soc. Class 4. Inspectoral Supervisory (Lower Crade), e.g. Department Manager, Guesthouse owner, Shopkeeper, Sergeant (Police), Shop Walker.

Soc. Class 5. Routine Monmmanal e.g. Barman, Caretaker, Fore. man, Rate Collector, Shop Assistant,

Soc. Class 6. Skilled Manual e. g. Baker, Bread Salesman, Cabdriver, Fricklayer, Builder, Painter, Welder.

Soc. Class 7. Semi-skilled Manual, e. A. Army private, Boilerman, Bus conductor, Car park atiendant, Fitter's mate, Postman.

Soc. Class 8. Manual, routine e. g. Cattie driver, Farm labourer, Factory worker, Porter.

For much of the analysis Social Classes 1 and 2, 3 and 4, 5 and 6 and 7 and 8 , had to be combined as the numbers concerned were small.

The pupils in our sample belonged to the following social classes :

TABLE 5

Fathers' occupational status by sex of pupil.

|  |  |  | Eoys | Girls |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | \% | $\%$ |
| Social Class 1 |  |  | 11 | 12 |
| 11 | 11 | 2 | 6 | 6 |
| 11 | 11 | 3 | 36 | 40 |
| " | " | 4 | 10 | 11 |
| 11 | " | 5 | 6 | 6 |
| " | 11 | 6 | 13 | 11 |
| 11 | " | 7 | 7 | 4 |
| 11 | " | 8 | 6 | 4 |
| Unemployed |  |  | 1. | 1 |
| Deceased |  |  | 1 | 3 |
| No Answer |  |  | 3 | 1 |
| Weighted base ( $=100 \%$ ) |  |  | 1,654 | 1,791 |

It is clear that the category containing by far the highest. percentage of both boys and girls in Social Class 3 - the category composed largely of farmers, but also including salesmen and primary and vocational school teachers.

It must be remembered that our sample is not a true reflection of the socio-economic structure of the total population in that we were concerned only with those pupils who were still attending schools and not with those who had already opted out of the educational system. Approximately $14 \%$ of 14 year olds and $29 \%$ of 15 year olds had discontinued their education and,
as we only included in our sample pupils in the Brd and subsequent year of post-primary education, we not only exciuded all these early leavers but also those who had not reached he intermediate certilicate year by the ime they were 14.

The distribution of these social classes amongst the school types is interesting and should be bome in mind when the analysis of the remainder of the survey is being discussed. The small numbers of pupils belonging to the higher social classes in the vocational schools and to the lower social classes in the Protestant schools meant that any attempt to partial out the relative importance of school type and social cless was likely to prove inconclusive. (Table 6)

TABLE 6 : Fathers' occupational status by school type.

| Urweighted base $(=100 \%)$ | 1.252 | 633 | 64 | 120 | 1,454 | 550 | 70 | 79 | groupings. It should be stressed, of course, that this does not mean that all high social elass pupils are studying in Protestant schools: far from it, only $10 \%$ of pupile from social classes 3 R: 2 were studying in Protestant schoois.

Very few of the sampled pupils were only children or had one brother or sister only. Almost $30 \%$ came from families of seven or more children and $4 \%$ had 10 or more brothers or sisters. As might be expected, of the schoois in the sample the Protestant ones had a much smaller percentage of pupits having four or more siblings, over $50 \%$ of them coming from families of only 3 or 4 chindren (Table A. 18 ).

Table. A 17 provides latween the tamily size of pupils in the survey sample (1970) with the uational population data of the 1961 Census. This total poputation data naturaliy does not deal solely with those in their third or subsequent year of phst primary education. One would expect those who persist in education to then third or subsequent year of post-primary education to be a very select group. f fact this does not appear to be the case. The selectivity is certainly less marked fhan that found among British pupils in retation to leaving school at age 15 (and it nust be remembered that most pupils in this survey were aged over 15). Although table A 18 which analyses early leaving in England by social class and bedroon deficiency, does not analyse the data in the same way as in table A 17 it presents an impression of a degree of selectivity in excess of that found in Ireland. Pbrhaps the explanation is that a higher proportion of pupils enter Irish secondary ochools than enter English grammai schools, and that fewer are thereby cut off from the possibility of real academic success. Perhaps there are fewer alternative openings for pupils coming from working-class backgrounds or fewer opportunities to ealm substantial amounts of money. Perhaps social class and family size are less good indices of the values anc̀ attitudes that are indexed by these things in England. Althdugh this last hypothesis is

Table A 17 (a) compares the social class and family size composition of the sample with that of the total population of "children" at the time of the 1961 census. There are a number of problems in interpreting the similarities and differences between the sample and the census data.

First it should be noted that the census data deals with all children born to the adults concerned; it therefore includes many children who would themselves have been adults at the time of the census, and many who would not yet have reached an age to enter the senior cycle of post primary education. As a result, from one point of view, since the census data includes many all-adult, and therefore complete, families, one would expect the cirains family sizes to be larger than those in the sample. However, as a result of the second difference between the bases of the tables, since the census table also includes young families, none of the children in which have reached the stage of post-primary education, and which are therefore more likely to be familues of le incomplete, thejchildren in the census would be: smalkafamilies than those in the sample. We wo nor know to what axient Thextwo conbery differances cancel each oherour.

Secondly it should be noted that, quite apart from the sorts of considerations discussed in the last paragraph, there have been several demographic changes, documented by Walsh (1972), and Hutchinson (1972), since the time of the 1961 census. Average family sizes have become smaller and the distribution of the population among the social classes has changed.

Thirdly, in order to make the CSO table comparable with our own, the Census column headed "Farmers, farmers' relatives and farm managers" has had to be incorporated into Hall Jones classes 3 and 4, and the census column "other agricultural occupations and fishermen" has been incorporated in Hall Jones classes 7 and 8.

In spite of these problems the comparison between the survey and the census data is interesting. Quite clearly pupils from the higher socio-economic classes are over-represented, and those from the lower social class backgrounds under-represented, among those who find their way into the senior cycle of post-primary education. The trends with fainily size are not so marked.

To facilitate comparison between the survey and the census data table 17 b has been prepared from the data in table 17a. The figures in this second table give the ratio of the obtained to the

The experved propankiso being based on the expected proportions of pupils in each cell, assumption that pupils from all backgrounds have equal talents and equal opportunities to stay on.

It will be seen that pupils from social classes I and 2, and from families of 5-6 children are present 2.7 times as often as would be expected on a proportionate basis, and that only 3 out of every 10 children who would be expected on a proportionate basis from families of 7 or more children of social classes 7 and 8 are in fact present in the schools.

To make the comparison still more striking table 17c gives the ratios in table 17 b converted to make the ratio for large, low social class families equal to unity. The effect of this is that all the participation ratios shown in the table are in terms of the number of times the observed propurtion exceeds that which would be expected if the pupils in the cell had the same chances of entering the senior cycle of post-primary education as low status children from large families. As a result it is obvious at a glance that children from families of 5 or 6 children of social classes 1 or 2 are present 9 times as often as would be expected if the same proportion of them as of children from large families of social classes 7 and 8 found their way into the senior cycle of post-primary education.

Attention must, however, immediately be drawn to the extreme sensitivity of these figures to the way in which they are calculated. Had the lowest ratio in table 17 b been .4 instead of .3 (as it might well have been, given the figure of .6 in the cell above), the highest figure in table 17c would have been 6.8, not 9.0. Furthermore, had social classes 1-4 been grouped together, as they have been in the English data presented in tables $18 a$ and $b$, the largest figure in the whole table would have been 4 .

Whatever the defects of the table, it is quite clear that, unless there have been really dramatic changes in family sizes since 1961, social class is a much more important correlate of participation in the senior cycle of post-primary education than family size. As a result it may be questioned whether economic constraint is in general a major deterrent from participation in the senior cycle of post primary education(which is not to say that it may not be important in particular cases). The relative unimportance of family size as a correlate of educational performance among Catholics has been documented by Cullen (1969) in Ireland and, as a correlate of participation rates, by Floud (1956) in England.

Before moving on it may be worth asking whether there might not be better ways of examining participation rates than through these ratio procedures. Indeed there would be ... if additional national statistics were available. If the census data by family size and social class were also available by age of child, and if a reasonable estimate of the total number of children, eligible on an age basis alone, for the senior cycle culabeobreined of post-primary education/, it would be possible to compare these figures with the sample figures grossed up to give the numbers actually participating.

In practice the relevant population figures
cannot be reliably estimated. Although census data giving the number of children of each social class is available by age, one cannot in fact specify the beginning and the end of the senior cycle accurately in age terms: Some of the relevant age group of pupils may be lower down in the school; others may have moved on into other forms of education. Even if rough age limits were selected there is no way of finding out accurately how many of each social class fall into each family size category, although they could, of course, be estimated using the proportions given in table 17a. As a result of the Ther wores. heve to be mace
number of approximations/one would be but little more certain of the answers than at present.

In the light of these considerations, and in the light of the fact that data being collected for the Minister of Education's Intermediate Certificate committee will enable participation ratios by social class at the time of the Intermediate Examination to be accurately estimated, we have not continued with this work. Had we done so the one thing it might have added to the Irtermediate Examination committee's work would be the relationship with family size. Yet this would be the most shaky part of the work, and we have already shown that, as far as can be judged from the present data, this appears to be a relatively unimportant variable.

How does this selective participation in
Ireland compare with other countries?
Table 18a gives the participation rates in England, as assessed in our sister survey. The table gives the actual proportion of the pupils who fell into each category in the table who stay on at school after 15 years of age. As we have indicated we would have liked to have collected
exactly parallel data in Ireland but this was not possible.
Table 18 b gives the English data converted to base rates calculated on the lowest cell in exactly the same manner as in table 17c.

Attention should immediately be drawn to the fact that the categories used in the analysis of the English data are much cruder than those used in the analysis of the Irish data: classes l-4 in the Hall Jones classification have already been merged together, and, as we have already indicated, if this had been done for the Irish data the participation differentials would have:been markedly reduced. Attention should also be drawn to the fact that the index of economic constraint used in the English study is a much better index of this construct than that used in the Irish survey.

In spite of these problems it would seem reasonable to conclude from a comparison of tables 18 b and I 7 c that, if the appropriate Irish data could be obtained, it would seem probabla that it would reveal a still more striking relationship than that documented for England in tabie 18a. Whether or not such a relationship is justified on the grounds of ability to profit frum the senior cycle of secondary education is a question that cannot be answered from this data. It is a question which we examine in part elsewhere in the survey.
supported by the data of Whoud (1056) and Cullen (1969), who found that only among very large famblies did one find thet fanty size had importan implications for educational perestence on performance among Cathohics in England and all pupils in Ireland respectively, It fails to explain why, as we shall see later, we do find rohationships just as strong as those documented in table A 18 when we study pupils' aspirations to go to miversity. Thus, although we do not know what the explanation of the difference may be, it does soem that, by British standards at least, entry into the higher levels of post-primary education seems to be quite unselecrive by thege variablea.

There were no signindint differences between the trends for boys and girls of the same social class and fromidy size. Thas it appears from table A 17 that social classes 1 and 2 are over sepresented in the later stages of post-primary education, that chidren irom chasses $5-8$ are under represented and that families of more than seven childen are under represented, particularly among children from social classes 7 and 8 .

#### Abstract

noteworthy in view of the fact that thome ame a mmber of lactons which might, in thomadves, explim the observed discrexancies between the sample charactexistics and the motional slatistice used, whout any allowance being made for seloctive emigration from, pe rotardation in, education by family fictor size or social class. One/te that the fyeyage size of family has fallen since 1961 , when the census data was gathered. A yeqage tanily sizes would therefore have been smallex if the mational data had beon collented at the time of the survey. Awothor factor is that the ig6t census asked for an children born alive to the present maxriage. This woudd berelore inolude entire families of children who had already leth school. Sipee these would more often be complete families they would be largex than the foreoten incompletefamilies included in the survey. Since these famhiesiwere older thoy would, in view of the decreasing family size, also be lajeer gn that oout too.

There is, however, a comer trend at work: The survey addressed itself to children in the thirdor subsequent year of postprimary education. Younger children (and thentefore families) would, as a result, have been excluded. These would naturally have been more likely to be incomplete, and thexefore smaller, families

As a result anl one can reaty say is that entry into the later stages of post-primary education, while somewhat selective by family size, is not so closely related as one might have expected
(1) Walsh, Brendan M., 'Trelands Demographic Transformation, 1958-170"' The Eoonomic and Social Review, Vol. 3, No. 2, January 1972.

Educational and Ocompational Aspirations

These variables will be malysed as dependent variables in n later report. Here we wish simply to give a pioture of the pupils in the sample. As can be seen from table ? oighteen plus is marginally the most popular school lenving age; $4 \%$ of the pupile twho, it will be romembered, had already reached inter cert year) hoped to remain at school until then. Boys studying in vocational schools were the most likely to intend to leave early (table A20), but it should be stressed that only about half of those intending to leave at 14,15 and 16 were studying in vocational schools.

Such pupils are not the monopoly of vocational schools.

| $\%$ | $\%$ | 9 |
| $14-10$ | 13 | 44 |
| 17 | 38 | 47 |
| $18+$ | 49 | 1,791 |

When they lewve school aute a large percentage of the pugils in the sample mond continuing with sume form of turther
 wiversity whe ib\% and 25 mospetively hous to have some other Com of fun tme tomer ecucation, awh as toacher traning. Protestant school puphls were the most hacty to be aming tor unversity While the pund in be vocationai shook were re most baely not to be ammang at anthing on to be aming at part-tho Iurther education (Toble A. 21).

The careors and jobs they hope to enter on leaving school include most of the occupations listed on any register of socio-economic status. Some pupils wre vory precise in their acpurations seating exactly the type of work they intend doing and the conditions under which they envisaged themelves working, e.g. "cooking in a hotel,' 'running a fire fighting eguipment business", 'junior partner to a solicitor;" while othens were nuch more vague preferring something such as an "outdoor job where you would be outdoor some of the time and indoor the rest", on "something to do with maths ${ }^{\text {" }}$ or "work which involves deep concentration and is very important to the community". The main jobs they hoped to enter are listed below and it is interesting to note that in both cases the teaching profession heads the list.

| Tobs hope to Enter | $\begin{aligned} & \text { Eoys } \\ & \% \end{aligned}$ | Jobs hope to Enter | Cinls |
| :---: | :---: | :---: | :---: |
| 'reaching | 14 | Teaching | 24 |
| Bulding | 9 | Wursing | 15 |
| Prof. Occupations <br> (Barrister) | 7 | Secret. /Shorthand typist | 11 |
| Fitter, Mechanic | 7 | General Office Work | 9 |
| Clerical and Office Work | 5 | Childrens Nenmy, Air hostess | 6 |
| Engineering | 5 | Medicine | 4 |
| Medicine | 4 |  |  |
| Weighted base ( $=100 \mathrm{~m}$ ) | 1,654 |  | 1,791 |

A mone detalled analysis of these aspirations will be presented later, bui it is worth memarking that, as would be expected, a much higher proportion of vocational school pupils hoped to go into the building trade and occupations suoh as fitters or mechanies among boys and secretarial/elerical occupations among girls.

Membership of Clubs, Societies and Libraries

In an attempt to examine some of the ways in which pupils occupy themselves outside the classroom they were asked to name any clubs or sacieties that they belonged to and also to indicate whether or not they were members of a library. As may be seen from table 9 , considerably more of the girls belonged to some type of library than did the boys and they were very much more likely to make use of the school library.

Both boys and girls at vocational schools were very likely not to belong to any library, followed by boys at Catholic secondary schools (Table SA1,2)but the fact thet ony $46 \%$ of the vocational schools in the sample had Libraries (Table A. 7 ) ought to be remembered. Library membership varied litte with intended age of leaning

IABLE 9.

| Library Membership | Boys <br> $\%$ | Girls <br> $\%$ |
| :---: | :---: | :---: |
| School | 27 | 40 |
| Other | 21 | 17 |
| Both | 10 | 20 |
| None | 37 | 19 |
| No Answer | 5 | 3 |

Although many schools provided quite a variety of clubs and societies, pupils were more inclined to belong to societies that were not organised by their schools, only $30 \%$ not neing nembers of some organigation externally run, while one half of them did not belong to any of the school cluus or societies, although only $19 \%$ of the schools did not organise some type of society. However, in some cases the choice may have been very limited or the actual quality of the societies poor. By far the most popular types of society were those concerned with sport, followed by externally run Youth Clubs including Scouts, Guides, etc. and then schoolbased Literary and Debating Societies (Table A23 \& 24). Protestant school pupils were very much more likely to be members
of the later and boys from such schools were more otten menbers of Arts and Crafts oitubs than pupils from other schoots but reference to Table As shows that their schools were much mone likely to have them than the of schools. Girls attodire vocational sohools were proporionately the most Whely to say that they were not mombers of any school based society or club while Protesiant schoots pupis, pamiculariy boys were the least likely to be nonmembers but again this is probably due more to the availability of clubs than to a deliberate policy of non-commitment.

## APPENDIX I

## GENERAL NOTES ON TABLES AND STAMXTTCS

WEIGHTED BASE : As explained earlier teachers and pupils in Comprehensive and Protestant sehools, and pupils in vocational sohools, were oversampled. In order to correct for this the responses of teachers and pupils in these schools were given leas weight than teachers and pupils in other schools when mating the statistical analysis. As a reeult the base on which the percentages are actually calculated are greater than the number listed as "weighted base". The result is that differences between groups are statistically more significant than would otherwise appear. The real base on which the percentages are calculated is given when the material is analysed by school type. This is the only case in which the true base is known.

TOTAL PGRCENTAGES: In very many cases informants could give more than one answer, with the result that percentages add to more than 100. Also, In most cases, as is inevitable in survey work, a small number of informants railed to answer each cquestion. The result is that percentages do not always add to 100. The amount by which the total percentages fall short of $100 \%$ can be taken as the non-response cate for each individual question.
STATISTICAL STGNIFICANCE: In view of the large sample size, in the majority of cases small percentage differences are statistically significant. The question then becomes, not one of statistical significance, but one of practical importance. In general we have not commented on differences unless they exceed $10-15 \%$. There are, however, other cases in which, even with a sample of this size, the sub-groups in terms of which the analysis had to be carried out if it was to have any meaning are very small. In these cases two questions present themselves: (1) Are the observed differences between the groups statistically significant; that is, what is the probability that one would get differences as large as those we have obtained if one drew the sub-groups on a purely random basis from the total sample? and (2) How near are the observed figures to the total population figures for each category of teachers or

#### Abstract

It is difficult to answer the firet question (a) because in many cases we have not antivged the whole distribution of ansiers but only one category e.g. those Who thought eiach objective "very jmportent", and (b) because we often had beveral bets of dita for each group of infoxmants - thus we have 8 bets of data relating to history teachers' responaes to the intermediate examination. It would therefore not be entirely appropriate to examine one aspect a time. Rather one should ask whether the overall pattern of history teachers' responses to this set of questions differed from the overall pattern of responses given by teachers of other aubjecta.

In spite of what has been said a generai guide to the statistical significance op difeerences between percentsges, which varies with the size op the groups involved and whether the peroentages are in the contre or the tail of the distribution, is given in the following table.

## Significance ot Diference Between Two Groups

Size of groups

35
50
100
200
300 400
\% Difference required for significance at $5 \%$ level around:

10 or $90 \% 20$ or $80 \% 30$ or $70 \% 40$ or $60 \% 56 \%$

As a guide to the use of the table one may give as an example two groups, each composed of 35 teachers, in which, on average, $90 \%$ of the teachers felt that the examination syotem performed a particular function $\operatorname{cofy}$ Well". In this case it would be neceasary for thepercentages
to differ by at least 15 (e.g. to be 80 and 95) for the difference to be significant at the $5 \%$ level. If the average for the two groups was in the general range of $50 \%$ they would need to differ by at least $24 \%$ (e.g. to be $40 \%$ and $64 \%$ ).

## Confidence Intervais

It is atso diricult to answer the setond gucstion, What conormed with the anfidence minevals to atad to the ousurved figuros whon gonerahizig to tho lotal population from which the sampie was
 and woighed sample. Naverthomes the following figures may be given as a guido.

95\% Comfidence Thervals.

| Size of Sample | Tmue (Population) probability (\%) |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 10 or 90 | 200080 | 30 or 70 | 40 ors 60 | 50 |
| 50 | +8 ${ }^{\frac{1}{2}}$ | $\pm 11 \frac{1}{6}$ | $\pm 13$ | $\pm 14$ | $\pm 14$ |
| 100 | $\pm 6$ | $\pm 8$ | $\pm 9$ | $\pm 10$ | $+10$ |
| 200 | $\pm 4$ | $\pm 5 \frac{1}{2}$ | $\pm 6 \frac{1}{2}$ | $\pm 7$ | $\pm 7$ |
| 300 | $\pm 3 \frac{1}{2}$ | $\pm 4 \frac{1}{2}$ | $\pm 5 \frac{1}{2}$ | $\pm 5 \frac{1}{2}$ | $\pm 0$ |
| 400 | $\pm 3$ | $\pm 4$ | $\pm 4 \frac{1}{2}$ | $\pm 5$ | $\pm 5$ |

Though this table is dcductive in type, i. e. designed for making inforences about the sample from the poputation it may be used approximately for the much more useful inductive process, i. e. for making inferences about the population from the sample. Thus if the sample size was 50 and the observed figure $10 \%$, then the true (population) figure has a $95 \%$ probability of lying between $1 \frac{1}{2} \%\left(10-8 \frac{1}{2}\right)$ and $18 \frac{2}{2} \%\left(10+8 \frac{1}{2}\right)$; if the observed figure was $50 \%$ the $95 \%$ confidence interval would be $36 \%-64 \%$.

It should, of course, be borne in mind that the margin of error would be considerably smaller than that indicated in the table when, as with our sample of comprehensive school teachurs, the sample contains a high proportion of the total population falling into that category.

## General Comments on Significance

More poworful ztatistical teehniques than those we have used are, of course, avathble. Howeyex due to some difficulties at the time of the analysis, these technigurs were not readily applicablo to our data. This, coupled with our desire to avoid unecessary delays in publication and further costs, is the reason we did not employ these more powerful statistical tools.

In addition, although more powerful statistical techniques would, of course, have been valuable, it is importani to bear in mind that, in work of this sort, the basic datat with which one is dealing does not justify elaborate discussion of fine detail. As a result tests of significance only become important when, although apparently striking results have been obtained, the numbers on which they are based are too small to give one great confidence in them. The remedy involves, not more elaborate tests of significance, but either or both more powertul techniques of analysis or: more probably, replication of the relevant part of the study with a purpose-drawn sample.

We would like to stress this last point particularly : where apparently important results have been obtained, but the sample size is too small to give one great confidence in the generalizability of the results, we would ask readers to avoid the sleight of hand involved in equating "not statistically significant" with "an insignificant result", and instead, to seek to initiate further studies which would find out, most probably by collecting additional data whether what appears to be the case is in fact the case.

Populations to be sampled: All head teachers, full time Post-Primary Teachers (i.e. those teaching 15 or more hours per waek) and full time Post-Primary pupils. Heads, teaohers and pupils in secondary tops, commercial and domestic colleges, and religious seminaries were excluded. (The population of pupils was later reduced to those in their thind or subsequent year of post-primary eflucation)

Sample Size: Previous experience suggested that a sample size of 1,200 teachers and 3,500 pupils would allow a reasonable exploration of most of the issues to be investigated. Although samples of this size would not make it possible to trace emerging relationships to their ultimate causes (such analytic studies commonly demand enquiries based on "experimental design" samples), it was felt that they should make it possible to speak with confidence about the situation prevailing in the population as a whole, and in the main sub groups within it. Having once obtained sound ractual information it would be more reasonable then to move on to design analytic. studies to tease out emerging relationships and to investigate potentially important topics in more detail.

Since it was envisaged that we would be expected to make statements about the situation existing within comprehensive, vocational, and Protestant schools, it was essential to obtain large enough samples of teachers and pupils within these school types, to permit confident generalisation. It was therefore decided to over-sample these groups.

As the data to be collected was expected to be of more than academic interest, in that it would probably be used in the formulation of policy, it was essential that it should accurately represent the views of the populations being studied. Not only does such a requirement entail large samples, it also entails that they be carefully drawn in order to be representative of the populations from which they are drawn. This in turn means that the non-contact and refusal rates have to be kept to an absolute
minimum. Postal surveys, conducted even where good-will exists, are inclined to encounter high rates of non-response. A more recent educational enquiry conducted by the ESRI in association with TEA can (postal)
be used to ilustrase this problem, 'his/sumey eicountered nonresponse rates of $21,5 \%$ of schools, and within the schoots that took part, $40 \%$ of the seachers and $12 \%$ of the pupils.

Such response xares obviously meke it impossibie to have any confidence in the generalizability of the results obtained. In practice the only way to avoid such rates of return is to uthize person-to-person interviews* Unfortunately personal interviews are extremely costly, especially if the sampie to be interviewed is randomly dispersed through the whole country. As a result it is normal to draw the sample in such a way that, although all areas of the country are proporionately represented, the interviews are clustered together within these areas.

Intially it was intended to ciuster the samples of teachers and pupils in 50 schools. However, owing to the small stee and diversity of the schools, this number had to be increased and the sampling unit in rural areas had to be chenged from schools to clusters of educational centres (each containing several schools). In all 181 schools were picked for the sample. Of these, 2 were novitiates, 3 were closed and one involved interview difficulties. Consequently the number of schools in the sample was reduced to 175 . Two extra convent schools were added to make the sample more representative. This brought the total number of schools to 177 . Nine of these 177 schools were for one reason or another unable to pax~ ticipate in the enquiry, leaving 168 to be visited by the interviewers. At this stage a further 7 found that the survey made too many demands on them, giving a final return of 161 schools. One of these however, had 3 campuses which had to be treated separately with the result that most of our report speaks of 163 schools. See Table 1.

* These iigures are a mixture which were obtained from the Department Educations' 1957 - '68 figures for Vocetional Sehools and 1968-169 figures for the rest. They exclude secondary Tops.
+ One vocational school had three campuses and was regarded as three schools in the analysis. This brings the obtained sample for vocational schools to 48 and the overall obtaned sample to 163.
o i. e. the sample as originally drawn
$f$ i. e. the sample of schools who returned data.
Response Rates. The above figures amount to a refusal rate of $4.4 \%$ of schools. 79 of the teachers who were approached fell unable to be interviewed, giving a refusal rate of $7.9 \%$ of the teachers. The response rate for the pupils is not known.

The original aim was to obtain representative samples of all full time post-primary teachers (i.c. those teaching 15 or more hours per wesk) and pupils. However, as a result of experience at the pllot stage, (which shoved that many pupils in the first two years of post primary education were undiet to cope with the questionnaires), it was necessary, in the absence of the funds needed to carry out personal interviows with puplis, to abandon the attempt to obtain data from a sample of aflpostuprimary pupils and, instead, to concentrate on pupils in their third or subsequent year of post-primary education (intermediate Certificate year and abovel.

For sampling purposes it was unfortunate that data of the detail we needed concerning the number of teachers in each school and the number of pupils in their third and subsecuent year of post-primary education in each schoot were not available in the form required in centrally compiled statistics. (This:
is in no sense a criticism of the Deparment's statistics; merely a statement that they were not avalable in the form in which we needed them for our, thusual, purposes.)

As a result, when drawing a sample of schools, the size of
both of these populations had initially to be estimated from total school size. This appeared to be a reasonable proxy variable for the number of teachers per school (espectally since it was believed thet the teacherpupil ratio was 1:22 in secondary schools, and 1:15-20 in vocational schools, although our own data was subsecuently to modify the overall ratio to $1: 16$ ) (see Table A2). However total school size was seriously misleading as an index of the number of pupils in their third or subsequent year in vocational schools: there were not even any national data (let alone in relation to each school in the country) concerning the number of pupils in each year of post primary education in such schools. The best proxy that could be obtained to the number of vocational school pupils who fell into the category we wished to sample was: all pupils in the senior cycle in such schools, plus all intermediate Certificate candidates, plus half the Group Certificate candidates. Furthermore, since 1967, the number of pupits in the senior cycle of Vocational schools has been increasing so rapidly that any statistics available at the time of the survey were seriously out of date. As will be seen later, this absence of accurate national information made it difficult to check on the accuracy of our final samples in vocational schools.

Using school size as an index of the size of the two populations in which we were interested, samples of schools were drawn separately for Protestant schools, comprehensive schools and other schools. All samples except those of comprehensive schools, which in any case comprised all schoots of that type, were stratified by Uroandeural and drea of the Country.

Mone Protestant and comprehensive schools were included in the sample than vould have been justiried on a strictly random basis. This was done in order so gei large enough numbers in these schools to permit generalisation about them. In fact whereas one in five of all post primary pupils in their third and subsequent year were studying in the selected nonProtestant, nor-comprehensive schools, one in three of all pupils studying in Protestant schools were in the selected schools, and, of course, all pupils studying in comprehensive schools were studying in comprehensive schools included in the study. This oversampling was later cornecied by gtatistical weighting when the material was being analysed,

In rural armas, for reasons which mill be discussed later, the primary sampling unit was olusters of educational centres rather than schools. In drban aneas the sampling unit was the individual school. Within strata, schools for clusters of educational centres) were selected with equal probability of selection, regardless of size. The weighted sample of schools Is therefore statistically representative of all schools.

Within all types of school, three-fifths of the teachers were selected for interview. The teachers to be interviewed were selected at random by ESRI staff from lists supplied by the Department of Education in the case of cetholic Secondary \& Protestan schools and from lists supplied by the Vocational Education Officers in the case of vocational schools. One-fifth of the pupils in their third or subsequent years were asked to complete questionnaires in all except vocational schools, where two-fifths were asked to do so, owing to the erroneously anticipated small numbers involved. The detailed sampling procedure followed within schools is described below

Although the general sampling procedure described here may seem logical, it is by no means automatically the best sampling procedure to use because, as can be seen for example from Tables A3 and A4 it results in the pupils (and therefore the teachers) from the large schools being concentrated in a few large schools - which may be highly matypical or sher lange solvols. Two other altexnative smping strategies were therefore considered. One way to avoid the problem is to proceed, as we did in the previously mentioned teA inquiry, to first sample schools with probability of selection varying with school size forobabity proportional to size) and then take equal-sized samples of teachers and pupils within schools, whatever the size of the school. This means that the sample of teachers and pupils from large schools is spread over a larger number of schools. This approach has the disadvantage that the sample of schools (although not of pupils or teachers) becomes urnepresentative and, in view of the small size of many of the schools, vexy many schools have to be visited to obtain a large enough sample of teachers This happens because small schools contain only a few teachers and this number determines the number of teachers to be interviewed in each school, whatever its sige. The second alternative, which avoids this difficulty, was used in the British sixth form inguiry. (1) In it, the sample was first stratified according to school size. Within strata schools were sampled with unit probability but the sampling fraction for both proportion of schools, and proportion of teachers and pupils within schools, varied with the strata such that, among the larger schools, the chances of the school being in the sample were higher than for small schools, and proportionately fewer of the teachers and pupils in such schools were interviewed (although the absolute number interviewed in any one large school was still greater than the total staff of the snall schools).

In Ireland this refinement was not introduced, partly because one could only apply it to the urban half of the sample, and also partly because there ware few very large schools. Nevertheless
(1) Morton-Williams, R, Raven, J. and Richie, J. (1970), Sixth Form Pupils and Teachers, Schools Council Publication, London.
the source of bias mentioned, namely that the 13 relatively large schools that appear in the sample may not be typical of all large schools (which between them cater for $20.3 \%$ of the total population of pupils) should be borne in mind. (cf. Tables A3 and A4). indeed $37 \%$ of the sample of non-Protestant, non-comprehensive, urban pupils (in Dublin) are located in only 12 large schools. This figure of $37 \%$ is based on school sizes in 1967-68 and 1968-69 and not on the actual size of the school at the time of the survey. The number of relatively large schools (i. e.401tj at the time of survey was 25 (cf. Table A11 (a) in the section "The setting of the Enquiry: the schools, the teachers, and the pupils").

## Sampling Schools: Rural Areas

The sampling procedure followed for non-Protestant, non-comprehensive schools in rural areas was to calculate the total number of pupils in all schools in each of the Department of Education's educational centres. These centres were then plotted on a map using a colour code to indicate size. Rings were then drawn around groups of centres in such a way that each cluster contained approximately 1,200 pupils - and hence, since the pupilteacher ratio in rural schools was belfeived to be $20: 1$, approximately 60 teachers. When two-thirds of these were selected at random for interview the result would be that each interviewer would have to interview 40 teachers. In practice, once the lists of teachers names were obtained it was found (Table A2) that there was actually one teacher to sixteen pupils, with the result that, in order to avoid obtaining too large a sample of teachers, the sampling fraction for teachers was reduced to 3 out of 5 .

Fandom sampling of clusters of educational centres was carried out within the four rural areas (or strata) into which the country has been divided. The representativeness of each of the samples so drawn was checked against regional statistics for school size. Tables A5 and A. 6 compare population and sample data for rural and urban areas.

## Sampling of Schools: Urban Areas

In Urban areas the sample was a three-stage one. First urban areas excluding Dublin were sampled (with unit probability), then, within the selected urban areas, schools, instead of clusters of education centres, were used as the sampling unit and again selected with unit probability.

## Protestant Schools

Protestant schools were sampled in the same way as urban schools - that is separately by 4 regions, using schools as the sampling unit, with unit probability sampling. (see Tables A7 and A8).

Comprehensive Schools

All comprehensive schisis in the country at the time of the survey were included in the sample.

## Sampling of Teachers within Schools

Having satisfied ounselves that the sample of schools was reasonably representative of the total population, samples of teachers and pupils were selected within schools. It can be said, therefore, that the sample, in addition to being stratified, was a two-stage one. (three in urban areas) The procedure for sampling teachers within schools was described on P4.

[^5]
## Interviewers Instructions for Selection of Pupils

All pupils in the intermediate year or equivalent, the Post-Intermediate year, or equivalent, the Leaving Certificate Year or equivalent, and any subsequent year are to be included in the groups to be sampled for the survey. If the school or any section of it does not take the Intermediate or Leaving Cerificate examination all pupils who would have been in these years are to be included. The pupils do not have to be taking courses leading to these examinations; it is the relevant age group that we are interested in.

Another way of saying the same thing is to say that we wish to include a sample of all pupils in the $3 \mathrm{rd}, 4 \mathrm{th}$, and 5 th years of secondary education. However this must not be contused with the schoolls method of numbering its classes unless the 3rd year is so called and is the Intermediate year and the 5 th year is the Leaving certificate year. Any pupils staying beyond the 5th, that is Leaving Certificate year, are to be included in the sample.

First obtain the class registers for each year. (If there is more than one class or stream in each year with a separate register obtain both (or all) registers for that year).

## Secondary, Comprehensive and Protestant Schools

In schools of this type we would like $1 / 5$ th of the pupils in the 3 rd , 4 th , 5 th or 6 th years of secondary education to complete questionnaires.

In order to ensure that these pupils are taken at random start with any register and count down from the first pupil on the list until you come to the fifth. This pupil should be included in the sample. Count 5 again, and again take the fifth, that is the loth on the list, and so on to the 15 th, the 20th etc. Unless the number of pupils on the register is a simple multiple of 5 there will be some
pupils left at the end when you have sampled the whole list. Write this remainder on a scrap of paper and start counting from that number when you come to sample your second regfster. For example, if there are 3 names left at the end of the first register you would count the first pupil on the second register as being pupil no. 4 and the second as no. 5, and thus include him or her in the sample. Thus in this case the second person on this regisier would be included in the sample as would the 7 th, the 13 th, the 15 th etc. If at the end of sampling all registers for the school you find that there are only one or two pupils left do not include any of them in your sample; if there are three, four, or five, include the last name on the register in your sample, It is not necessary to sample boys and girls or to sample years separately.

## Vocational Schools

In Vocational Schools ve would tike 2/5ths of the pupils in the 3rd, $4 \mathrm{th}, 5 \mathrm{~h}$, or 6th year to complete questionnaires.

A sample of this size will be achieved as follows: take the first register so hand, and count down until you come to the 3rd pupil. He should be included in your sample. Then count 2; this second pupil (the fifth on the list) should also be included in the sample. Then 3, then 2 etc. so that you include in your sample the following pupils: Pupil no: $3,5,8,10,13,15$ etc. Again note the number of pupils remaining at the end of the first register and bear this in mind when you start counting on the second register.

It does not matter in which order the registers are sampled, the object being to obtain a random sample.

At the end of the last register if two names remain after the last pupil has been sampled include the last pupil in the list in the sample.

Substitution of Absent Pupils
If pupils are absont on the day you have arranged for them to complete the questionnaire or if ineir parents do not agree to let them complete questionaixes, do not substitute anothex pupil; return the uncompleted questionaire stating reasons for non contact.

Reason for Over-Sampling Vocational Pupils
The reasons for ovexsampling vocational school pupils was that it was originally estimated, on the basis of secondary school experience that only senior cycle pupils and those taking the intermediate certificate examination would be in their third or subsequent year of post-primary education. This would have yielded less than 300 pupils in vocational schools, distributed throughout the country. In order to increase confiden in this sample the sampling fraction within schools was doubled, and this was expected to yield 500 to 600 pupils. In point of fact it yielded 1, 183

This is partly explained by the fact that the number of pupils in the senior cycle of vocational schools increased from 3, 080 at 1 Feb. 1969 (The lateat figures available prior to the survey) to 7,739 at 1 Feb. 1971 (The group of pupils we contacted in the previous october).

Our original estmate of the numbor: of punis whe hard or subsequent

 expergenve it was assuned mat sroup - come was taken from the
 although it is clear that they ehond bave been. The propotion to be included remains doubtul. Eut it is lean that when they are added, and allowance is made for the increasimg numbers of senion cycle pupils in vocational schools, the manber/is not unceasonable.

## Checks on the Representativeness of the Samples

Atterpes were made to theck on the representativeness of the samples at various stages.

As has already been reporrea the sample of schools was checked against population daka prion to the schools being approached for co-operation (see Tables A 2 to AB).

Thereafter every effort was made to obtain the comoperation of the selected schools. Nevertheless, for a variety of reasons, not all the selected schools felt able to co-operate in the enquiry. Although it is a departure from rigorous sampling practice, substitutes were drawn for 2 of the schools who felt unable to cooperate. These substitutes were drawn from sub-samples of schools of the same size, type and area. This was done because of the distorting effect that the absence of up to 80 pupils and 12 teachers fin the case of large schools) might have on the representativeness of the sample in one of the strata. The reason why this represents departure from rigorous sampling practice is that schools who refuse to cooperate are clearly, by that very fact, different from more cooperative
substitube shools. It will neron be known whother the differences genoratise monters that aro relovant to the survey.

Ghe we whew whob schools and agrod to cooprate a furtho check was made on ho ropresentawones: of the sumple. The 1067-63 stathtios For Vontiona schools and we $1063-69$ statistics for fecendary senools were geain used, nod totel mumber pupils in the school was again used as a proxy for both mumex of teachers and number of puphe in third, fourd, fith and sixth years of post-primary education, Examples of this material is given in Tables A.5 and AG (under the hoading actual cooperating sample).

A final sextos on cheoks wexemate once all the naterial had been processed and weighted. Those are givon in Tables A9, to ATB,

Sunming up

In conclasion, then, we may say that the sample of tomehers apperas so conform very ctozoly to the total population of beaches insohar as it con bowtrated rom total sohool size. The sample diverges litule from he estimate in terms of region, school sire, school type, or arbanmed characteristics.

We can be less cextain about the quality of the pupils' sample owing to the difficulty of estimating the namber of pupils in the third or subisequent year of postmprimery education.

In spite of thas the sample of shools from which the pupis were arawn cloesty mirrors the characteristics of the total population of achools,

Although it is montr ot the somple it must continuously be borne in mind that, owine to the fact that we have sarmpled ony pupils in their thind or subsequent year of post-primary education, the 13 and 14 year old pupils included in the sample ane highly a-dypical of 13 and la year olds in the total popuation.

## Notes on the Tables

The figures given in most of the following tabtes are based on $1567-6 e$ statistics in the case of vocationat schoois and puplls and $1968-69$ statistos in the case of secondary schools and pupits. This apose beduse the $1968-69$ list pi recognized posi primary schools did noz contain pupil numbers in vocational sctrouts.

The tables were drawr up to examine the representativeness of the samples. Most of the columns were dotalned from official statistics and do not represent the situation in the schools at the time of the survey. Thus it had to be assumed that if the samples were representative of the populations from which they were drawn the changed populations in the senools at the time of the survey would be representative of the changed stal population at the time of the survey. The figures which appear in the columns labelled"target sample" and "actual cooperating sample" are therefore all in terms of the same basic statisticss they do not reter to the situation prevaling at the time of the survey.

The figures in the "obtained sampleir columns do give the figures at the time of the survey. fowever, since the purpose here is to examine the adequacy of the sample, the analysis here is in terms of the $1967-58$ or $1968-69$ size of school, and not in terms of cize of school at the time of the survey.

Notwithstanding what has been said table Ag which does not involve reference to the detalled strata involved in the survey, is based on 1969-70 statistics and on the actual returns from the survey in October-November 1970.

The numbers used in the diagram for the school system are from a table supplied by the Department of Education and titied "Number of Persons Receiving Full-Time Education on 1 st February 1969".

$$
-516 \ldots
$$

The population dgures fox Thbles A10 to A13 are based on statistics for 1969-70. The numbers in the colurns and cells headed "Obtaned Sample of Post-Primary Pupils" for Tables Alo and 111 were weishted as follows -
voctionals $X \frac{1}{2}$ : momprehensives X $1 / 5$ : Protestants X $3 / 5$

In the Tebles Al2 and Als the word "Secondary" means Catholic Sesoxtary and Protestant achool teachera. The numbers of Protentan teschens included were weighted by 3/5. No similar date was available for tae Popudation of vocational and comprehensive teachers. The ony avalable and relevant breakdown were by (a) sex and (b) religious or iay, and this ority for secondary school teachers. Further comperisons of ottaned sample data with relevant Population data would have been illuminating, had such Population data been centraliy available.

Tables A2 to A6 exclude mroteatant and comprehensive schools.

[^0]:    * Human Relations, December 1972.

[^1]:    *As 1 school had 3 separate campuses it was dealt with in the analysis as 3 separt schools so future tables refer to 163 schools.

[^2]:    * See, for example, Oppenheim, A.N. Questionnaire Design and Attitude Measurement, Heinemann, London, 1966.

[^3]:    Occupations which less than $2 \%$ of the sample hoped to enter have been omitted.

[^4]:    * These, of course, have many other advantages over postal surveys.

[^5]:    Emolina of Pupils within Schools

    Whereas the Department of Education had supplied lists of the names of teachers in the selected schools, names of pupils could not be obtained without visiting the schools. The selection. was therefore made by ESRI interviewers on arrival in the schools following the instructions given below.
